

Methods and apparatus for managing information related to backup storage activities of data storage systems. In a computer system having one or more independent backup data storage systems coupled to each other and each serving one or more clients, a user may obtain information related to backup activities of any of the backup storage systems from a single location. Through a user interface associated with any of the backup storage systems, or through a stand alone user interface, a user may manage (e.g., organize, display, print) information related to backup activities of any or all of the backup storage systems. System administrators can design and store a variety of report formats that may be utilized by any user to display or print various parameters associated with backup activities in a particular manner. Report formats may be edited by users, and displayed parameters may be dynamically updated to provide for active monitoring of one or more backup storage systems. Additionally, periodic backup activity reports can be generated and automatically sent to designated locations, for example to one or more printers and/or to one or more designated recipients via E-mail.
